Hepatectomy for gallbladder-cancer with unclassified anomaly of right-sided ligamentum teres: A case report and review of the literature

Goto T, Terajima H, Yamamoto T, Uchida Y
World Journal of Hepatology (World J Hepatol, WJH, online ISSN 1948-5182, DOI: 10.4254), is a peer-reviewed open access academic journal that aims to guide clinical practice and improve diagnostic and therapeutic skills of clinicians.

WJH covers topics concerning liver biology/pathology, cirrhosis and its complications, liver fibrosis, liver failure, portal hypertension, hepatitis B and C and inflammatory disorders, steatohepatitis and metabolic liver disease, hepatocellular carcinoma, biliary tract disease, autoimmune disease, cholestatic and biliary disease, transplantation, genetics, epidemiology, microbiology, molecular and cell biology, nutrition, geriatric and pediatric hepatology, diagnosis and screening, endoscopy, imaging, and advanced technology. Priority publication will be given to articles concerning diagnosis and treatment of hepatology diseases. The following aspects are covered: Clinical diagnosis, laboratory diagnosis, differential diagnosis, imaging tests, pathological diagnosis, molecular biological diagnosis, immunological diagnosis, genetic diagnosis, functional diagnostics, and physical diagnosis; and comprehensive therapy, drug therapy, surgical therapy, interventional treatment, minimally invasive therapy, and robot-assisted therapy.

We encourage authors to submit their manuscripts to WJH. We will give priority to manuscripts that are supported by major national and international foundations and those that are of great basic and clinical significance.

World Journal of Hepatology is now indexed in Emerging Sources Citation Index (Web of Science), PubMed, PubMed Central, and Scopus.
Large primary hepatic gastrinoma in young patient treated with trisegmentectomy: A case report and review of the literature

Abstract

Primary hepatic gastrinoma is a rare disease, with fewer than 40 cases reported in the medical literature. Because it is located in an organ in which metastases are common, its diagnosis is difficult. We report a case of a 19 years old male patient with a history of gastric
ulcers since the age of nine. Following gastric surgery, an antrectomy and a vagotomy, there was some alleviation of symptoms. Subsequently, the patient reported various intermittent episodes of diarrhea, diffuse abdominal pain, and vomiting. The patient underwent tomography, which revealed the presence of a hepatic mass measuring 19.5 cm × 12.5 cm × 17 cm. Primary hepatic gastrinoma was diagnosed based on laboratory examinations that indicated hypergastrinemia and a positron emission tomography/magnetic resonance study with somatostatin analogue that confirmed the liver as the primary site. After hepatic trisegmentectomy (Ⅱ, Ⅲ, Ⅳ, Ⅴ, Ⅶ), the patient’s symptoms improved. The case is notable for the presence of a rare tumor with uncommon dimensions.

**Key words:** Gastrinoma; Primary hepatic gastrinoma; Zollinger-Ellison syndrome; Hepatic trisegmentectomy; Gastric surgery

Core tip: Primary hepatic gastrinoma is a very rare disease. Due to its location in an organ in which metastases are common, its diagnosis is difficult. We report a case of a 19 years old male patient with a history of gastric ulcers since the age of nine. Hypergastrinemia and a PET/MR study with somatostatin analogue confirmed that the liver was the primary site. After hepatic trisegmentectomy, the patient’s symptoms improved. The case is notable for the presence of a rare tumor with uncommon dimensions.

**INTRODUCTION**

Zollinger-Ellison syndrome[1] is characterized by gastric hypersecretion, resulting in peptic disease and diarrhea[2]. Diagnosis is confirmed by gastrin levels of over 1000 pg/mg. This syndrome was first described by Zollinger and Ellison[2] in 1955. With an incidence of around 0.5 to 2 per million, the majority of patients are diagnosed between 20 and 50 years of age, with a higher prevalence among men. The majority of gastrinomas are sporadic, and 20%-30% are associated with type 1 endocrine neoplasias, NET-1[3].

The classical clinical presentation of the syndrome is the presence of abdominal pain (75%) and chronic diarrhea (73%). Half of patients present with burning as a result of gastroesophageal reflux. There is still a significant population (17%-25%) that presents with weight loss and gastrointestinal bleeding[4]. Over 90% of cases of gastrinomas are present in the so-called “gastrinoma triangle”, delimited by the cystic duct, the junction between the second and third portions of the duodenum, and the junction between the colon and the pancreatic body. Occasionally, gastrinomas have also been described in other areas, including lymph nodes, biliary tree, ovaries, kidneys, heart, gallbladder omentum, and liver[5-7]. This article describes a case of primary hepatic gastrinoma in a 19 years old hypergastrinemic patient who underwent hepatic trisegmentectomy to remove the tumor.

**CASE REPORT**

A male patient, 19 years of age, was referred as a result of intermittent abdominal pain over the previous 10 years. He reported an attack of diffuse abdominal pain for 1 month at the age of nine. At that time, a gastric ulcer was diagnosed, and due to the failure of clinical treatment, he underwent antrectomy with vagotomy in another service. In the years following the surgery, the patient presented sporadic episodes of non-specific diffuse abdominal pain associated with nausea and vomiting. Diarrhea was also present, but dyspeptic characteristics were not. During that time, emergency treatment was sought with regularity, with improvement following clinical treatment. A loss of around 16 kg of body weight was reported over the year prior to admission to our service (from 68 to 52 kg).

Upper digestive endoscopy was carried out. In the third distal, close to the esophageal transition, the mucosa was pearlescent and thickened, which was associated with confluent erosions larger than 5 mm. This covered 100% of the circumference of the organ, with ulcerations and fibrin (intense erosive distal esophagitis-Los Angeles Class D). Furthermore, an image compatible with extrinsic compression of the stomach was revealed (Figure 1).

Computed tomography (CT) and magnetic resonance (Figure 2) were carried out, showing increased dimensions of the liver, as the result of a voluminous expansive hypervascularized lesion with necrotic central areas. Involvement in the portal vein was identified, and the mass mainly occupied the central portion of the liver and hilum, affecting segments Ⅰ, Ⅱ, Ⅲ, Ⅳ, Ⅴ, Ⅶ and measuring 19.5 cm × 12.5 cm × 17.0 cm.

A biopsy was carried out with the following immunohistochemical characteristics: cytokeratin 7 negative, cytokeratin 20 negative, chromogranin positive, synaptophysin positive, CD99 positive, Hep par 1 negative, polyclonal CEA positive (standard cytoplasma and membrane), and Ki 67 positive (around 5%). It was concluded that the profile was compatible with a well-defined neuroendocrine tumor (NET Grade 2). The diagnosis was confirmed by the discovery of gastrin hypersecretion, via chemiluminescence, with a resulting

carried out - PET-MR - with somatostatin analogue (Figure 3). The examination was carried out following the administration of 2.7 mCi of Ga68-DOTA-Octreotate (68Ga-DOTATATE) intravenously. The examination showed a relatively well-defined expansive lesion on the liver, with lobulated contours, situated in the left lobe. Heterogeneity in T2 and an anomalously high concentration of radiopharamcus was noted. It was heterogeneously distributed, with central and peripheral areas with hypoconcentration of radiotracer (which can correspond to necrosis/liquefaction), measuring around 18.1 cm × 11.3 cm at the largest axes. Contact and constriction of the inferior vena cava, which was permeable, were sustained. There were no signs of invasion of the head or body of the pancreas.

From these examinations it was possible to confirm the diagnosis of primary hepatic gastrinoma and to recommend surgical resection. Prior to the surgical procedure, there were a number of intracavity adherences. Hepatic trisegmentation (II, III, IV, V, VIII) was carried out (Figure 4), identifying a large volume mass, mainly occupying the left lobe of the liver. Segments V and VIII were most affected, with atrophy in segment II, as well as compensatory hypotrophy in segments VI and VII. The remaining liver maintained approximately 80% of the volume of a functional liver. The value of 6709.0 pg/mL.

Considering that the liver is a common location for metastasis, it was important to define whether or not the tumor was primary. To do this, positron emission tomography associated with magnetic resonance was...
The patient was readmitted in the early postoperative phase with abdominal pains and leaking of bile through the drain due to a biliary fistula. The patient was submitted to a surgical procedure with a good outcome. Six months after the resection, the patient was well, had no relapses, and had a gastrin level of 40.5 pg/mL. At 1 year after the surgery, exam showed a gastrin level of 89.2 pg/mL. The normal range of gastrin is 13 to 115 pg/mL.

DISCUSSION

Zollinger-Ellison syndrome (ZES) is predominantly sporadic, although in 20%-30% of cases its origin is type 1 multiple endocrine neoplasia (MEN1). MEN 1 is a genetic disease that occurs in the gene MEN1, leading to the formation of various neoplasias; pancreatic endocrine tumors, pituitary adenomas, and hyperplasia of the parathyroid are the most prevalent. Despite the evidence of ulcers in this patient at the age of nine, ZES should be considered, principally because of the patient's history and hypergastrinemia. There was no report of the occurrence of MEN1 together with primary hepatic gastrinoma, including in our case.

Gastropancreatic neuroendocrine neoplasias, which can cause ZES, are classified according to their prognosis. Well-defined neuroendocrine tumors have a clinical course that is much less aggressive and can be subclassified as G1 (Ki-67 < 3) and G2 (Ki-67 of 3%-20%), according to the Ki-67 index that assesses the level of differentiation of cells in tissue. Poorly defined tumors are in category G3, presenting Ki-67 > 20%. Histopathological analysis of the patient’s tumor revealed a Ki-67 of 5% (G2)\(^6\). The most common gastrinomas, duodenal and pancreatic, present a mean diameter of 1 and 3 cm, respectively\(^9\). The tumor in this case had dimensions of 19.5 cm × 12.5 cm × 17.0 cm.

Primary ectopic gastrinomas are neuroendocrine tumors located outside of the triangle of gastrinoma and are responsible for less than 10% of cases. One specific site in which they occur is the liver, with only 26 cases described in the literature in a review from 2012\(^10\). In recent years, there were a few more cases described, but the total number is still very low. According to a recent study\(^11\), in ZES patients, primary gastrinomas of the liver were the second most common extrapancreatic, extraintestinal site for a primary gastrinoma and may metastasize to regional lymph nodes. Compared with typical ZES patients, the epidemiology of primary hepatic gastrinoma is a little different. The patients are generally affected much younger, with a predominance of males and no association with MEN 1, as it was in our case\(^12\).

This rare hepatic gastrinoma is slow growing, with around 65% of cases malignant and 30%-40% of those cases being metastatic at initial presentation. This relatively high rate of metastases arises from the difficulty of diagnosis, especially in palliative care and hepatic metastases\(^13\). Despite this, our patient did not present metastases in radiological examinations.

A clinical presentation of ZES similar to gastroesophageal reflux can lead to treatment with proton-pump inhibitors. This medication masks the symptoms and alters gastrin levels, prolonging the time necessary to identify the real cause of the disease. A study\(^14\) showed that prior to widespread use of proton-pump inhibitors (before 1985), the rate of metastases was only 19%. Ten years later; this number had risen to 55%. Prior to the advent of proton-pump inhibitors, partial and full gastrectomies were common to reduce the incidence of ulcers. In the report of this case, the fact that the patient had previously undergone antrectomy with vagotomy meant that his symptoms were less apparent than they would otherwise have been.

A second factor that can complicate diagnosis is related to the morphofunctional characteristics of the liver. It is known that the liver is a common site of metastasis for a variety of tumors, and classifying the neoplasia as primarily hepatic requires some examinations to confirm the absence of other primary sites. One of the examinations currently used is PEC/CT with 68 gallium-dotatate. This radiopharmaceutical is associated with computerized tomography and is a somatostatin analogue, which allows the identification of tumors\(^15\). The sensitivity of the examination was 93% (95%CI: ± 2%) and the specificity was 91% (95%CI: 82%-97%), as identified in a meta-analysis\(^16\). Once the neuroendocrine tumors present somatostatin receptors, it is possible to confirm whether the hepatic

**Figure 4** Intraoperative appearances. A: After hepatic posterior sector mass separation; B: Aspect of the remaining liver after surgical removal; C: Surgical piece.
gastrinoma is primary or the result of metastasis. In this case, the existence of a single focus in the liver combined with a high level of gastrin highly suggested it as a primary site. It is important to emphasize the importance of the follow up of gastrin levels to ensure that there is not a small small duodenal primary gastrinoma that could not have been detected in the PET/CT and surgery.

Despite few reported cases, surgical resection should be the treatment of choice and, furthermore, the only chance of a cure. The rate of success in these cases is 86%, and 60% present early postoperative euagastremia, 40% after five years. In the event that surgery is not possible, such as in cases of diffuse metastasis or comorbidities, it is possible to follow conventional treatment: Ablation by radiofrequency, chemotherapy (doxorubicin, streptozocin, 5-fluorouracil), interferon, and transplantation. A study with 160 patients with gastrinoma showed that 15-year disease-related survival was 98% for operated and 74% for unoperated (P = 0.0002).

In conclusion, primary hepatic gastrinomas are extremely rare tumors that cause Zollinger-Ellison syndrome. Due to their clinical presentation and the liver being a significant site of metastases, diagnosis of the disease is time consuming and difficult. Following diagnosis, the treatment of choice is surgery, and, in cases where there are no metastases, the prognosis is good. Therefore, it is important to diagnose properly the primary gastrinoma.

**ARTICLE HIGHLIGHTS**

**Case characteristics**
Primary hepatic gastrinoma in a 19 years old hypergastrinemic patient who underwent hepatic trisegmentectomy to remove the tumor.

**Clinical diagnosis**
Primary hepatic gastrinoma.

**Differential diagnosis**
Gastrointestinal tumors, MEN 1.

**Laboratory diagnosis**
Gastrin levels were 6709.0 pg/mL before surgery. After the procedure it was 40.5 pg/mL.

**Imaging diagnosis**
Computed tomography (CT) showed a voluminous heterogeneous hepatic lesion, with a neoplasic aspect and dimensions 19.5 cm × 12.5 cm × 17.0 cm.

**Pathological diagnosis**
Histopathological analysis of the patient’s tumor revealed a Ki-67 of 5% (G2).

**Treatment**
Hepatic trisegmentectomy.

**Term explanation**
Gastrinoma: A gastrinoma is a tumor that secretes an excess of gastrin, leading to ulceration in the duodenum, stomach, and the small intestine.

**Experiences and lessons**
Primary hepatic gastrinoma is a very difficult to diagnose. Meticulous examination is necessary for appropriate diagnosis and treatment.

**ACKNOWLEDGEMENTS**
The authors are thankful to Justin Axel-Berg for the English corrections.
